# ABSTRACT

Chinese urban realities, and in particular Shanghai, reveal a model of complex urbanity that exaggerates the timing and consequences of socio-economic change in cities. Shanghai, like the rest of China, is characterized by a high density of housing. The motivation of the study is to find a way to design a mix functioned high rise building to meet the very current need of housing, due to high population density in the city; while taking the user profile, habits, urban realities and conflicts into consideration to suggest a new way of living in verticality in the context through the synthesis of the needs of the context, users, and the city.

The choice of the place for the project, Pudong district, was consciously made after understanding of the urban development of the city, drastic demographic changes which it has been through, the effects on modernisation, globalisation, as well as keeping the cultural background with the history of the city.

Being a newly developing district transformed partially from industrial zone of the city, has its own characteristics and challenges to be considered with the suggested design proposal.

With the awareness of all the analysis that has been made, to get a better understanding of the chosen context for the project, formed the concept naturally: a proposal to introduce a new way on living in the 'high rise'.

As the relation the building will have with the context surroundings are carefully considered, the challenges of design of mix used buildings are also noticed and carefully considered, as underlined before importance given to the analysis of the user habits and cultural solutions through time; not only to physical aspects of a courtyard, square or a house, but also to consider the aspects and relations that they are forming; within the role they play in the context for placemaking, needed for creating a better and sustainable way of living on vertical.

# THEME & PLACE

Many Asian cities are experiencing a population explosion and economic expansion, the unprecedentedly rapid rise of the urban scale in the early 21st century is leading to the creation of megacities with populations exceeding 20 million.

With an exploding population migrating from rural areas and small towns to large cities, particularly in Asia, residential and commercial/mercantile accommodation problems continue to magnify. The future of these cities lies in the inevitable construction of high-rises unless an alternate solution is found for creating architectural spaces, and efficient infrastructures.

On this point, to analyse the conflicts that are being faced on the existing design of high rise for housing, understanding the needs of the context and the residents becomes a crucial point for the study of new ways of living vertical.

---

# THEME: TALL BUILDING

Tall buildings through years:

## From tall to supertall, supertall to megatall, adaptation of definition of tall building:

The definition of 'tall', however, has changed over time. According to the definition given by CTBUH, a 200 m+ building is 'tall', 300 m+ is 'supertall' and 600 m+ is 'mega tall'. Advanced technology in building construction and elevator systems, among others, pave the way for skyscrapers to grow taller and taller.

Today's super-tall buildings are no longer single-purpose skyscrapers, rather they are considered mixed-use vertical cities with many facilities and functions available to occupants & users. Structures such as the Burj Khalifa, Shanghai Tower, and Kingdom Tower, as cases in point, take the typology in unprecedented directions.

The more it becomes this tall building typology gets into people life, hosting and serving the living, working / service spaces, the more challenges it brings with itself; social sustainability, energy aspects, architectural quality, humanistic approaches based on the users...

As well as these key points highlight the quality of the architecture of tallness; it is undeniable that they have significant visual impact on skylines of the cities.

It is important to notice not only how it is perceived from distance yet also to consider the close context relationships that they are forming; within the role they play in the context for placemaking. needed for creating a better and sustainable urban fabric.

Figure 2: Tall buildings in 2000 and 2020, In recent years it has been built more tall buildings with greater height.

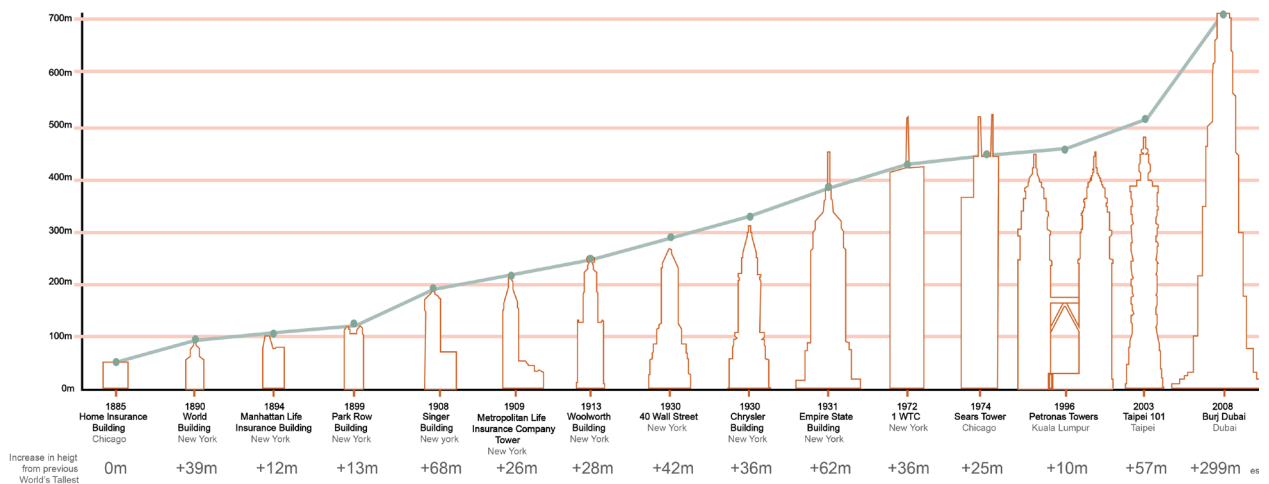

Figure 4: Tall Buildings in 2000 and 2020. In recent years, we have been building more tall buildings with greater heights. In addition, buildings "under construction," "proposed," or "visionary" categories feature greater heights. Shaded rows highlight the supertall and megatall categories.

## Tall building reasonings:

Figure 5: World Population Data and dispersion in between rural and urban- Reality and prevision for future based on pattern

### Population Increase and Migration:

Among the major problems that have prodded tall structure advancement, and will probably proceed, is the outstanding expansion in metropolitan populace worldwide related to abundance collection. Right now, the greater part of the world is metropolitan when 20 years prior it was only 33%. By 2030, it is normal that around 60% of the total populace will be metropolitan.

### Demographic Change:

Segment shifts exhibit that a large number of the twenty to thirty year olds incline toward living in metropolitan communities that offer social conveniences, energetic public activity, and mass travel.

### Global Competition and Globalization:

The continuous pattern for developing tall structures all over the planet reflects the expanding sway of worldwide rivalry on the improvement of the world's significant urban areas.

These urban areas contend on the worldwide stage to have the title of the tallest structure where to declare the confidence and worldwide height of their developing economies. A notorious tall structure improves the worldwide picture of the city. It is probably going to put the city on the world guide and flag or advance its significant monetary advancement and progression.

Figure 6: Population of Cities with 10 Million Inhabitants or More, 1950, 1975, 2000, and 2015 (in millions)

## Urban Regeneration:

As mentioned before, downtown areas in created nations that experienced the relocation of their populace to suburbia in the 1970–1990s have seen a significant re-visitation of their focuses as of late. In this manner, urban communities are seeing a metropolitan renaissance and a craving to get back to skyscraper living in the metropolitan centers. Tall structures are seen as apparatuses to support focal living and working.

## Infrastructure and Transportation

The high cost of maintaining expansive infrastructure hurts taxpayers and contributes to the fiscal crisis that local governments face. Largely, vertically configured buildings facilitate more efficient infrastructure. Simply put, a 500-unit single-family subdivision requires many more roads, sidewalks, sewers, hydro lines, power and gas lines, light standards, and fire hydrants than that of a tall building, which allows integrating these systems efficiently in a dense manner.

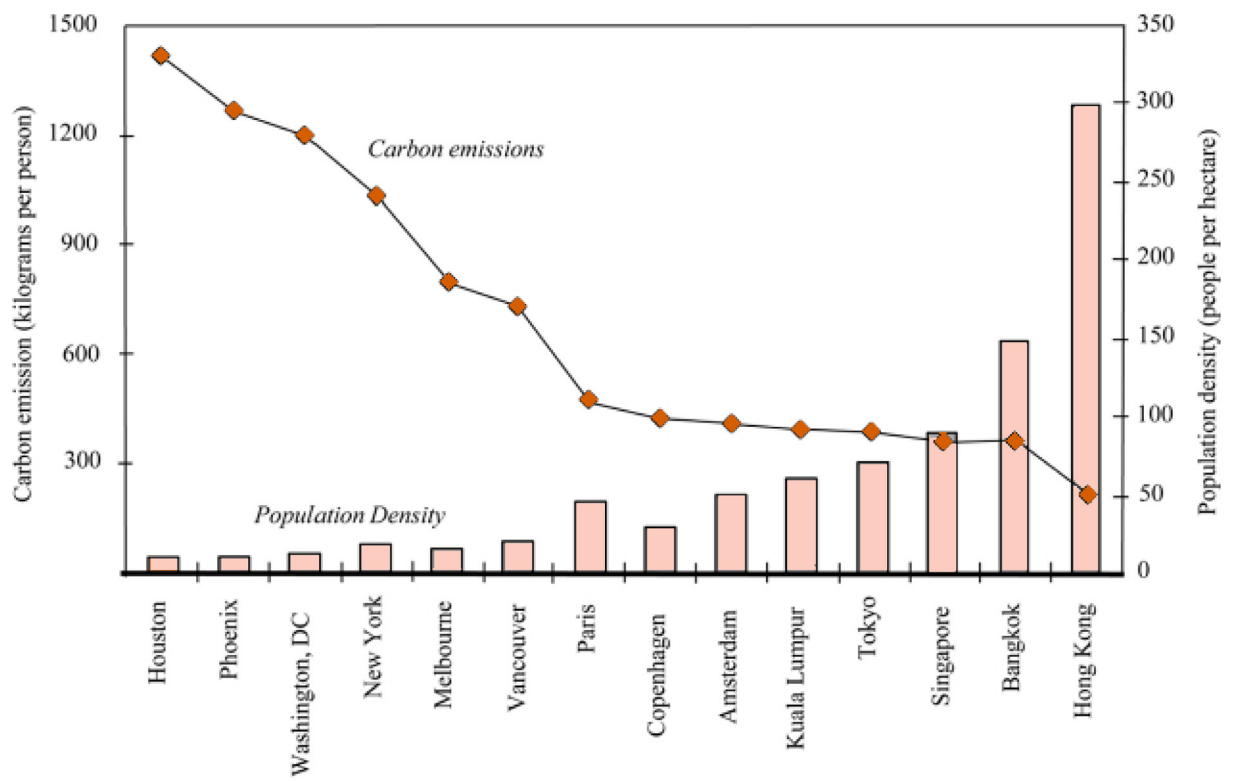

Figure 7: Tall buildings in 2000 and 2020, In recent years it has been built more tall buildings with greater height.

# THEME: TALL BUILDING

## Climate Change and Energy Conservation

In this context, tall structures have the potential to burn-through less energy than low-ascent buildings since they have a few energy-effective attributes, for example, agglomeration, reserve funds in auto fuel and travel time, and a decrease in misfortunes in power lines. The rooftop is an excellent wellspring of energy misfortune in a structure notwithstanding the façade.

All things considered, a 50-story working of 10 lofts for every floor has one rooftop and 500 single-family homes with each having the equivalent floor space of a condo with 500 rooftops. Energy misfortune from 500 rooftops is more noteworthy than that from one rooftop.

Generally speaking, vertical advancement diminishes fossil fuel byproducts as well as also provides freedoms to establish reduced conditions that highlight efficient portability and openness while offering a more excellent of life.

“Minimized, blended use, walkable, travel arranged spots offer significant ecological, financial, and social benefits”

## Land Prices:

Land prices have been a prime driver for constructing tall buildings. A phrase for skyscraper came from Cass Gilbert in 1900, “A skyscraper is a machine that makes the land pay”.

## Land Preservation

Sustainability promotes compact urban living and vertical density is viewed as a tool to create a more sustainable city.

The availability of open space provides significant environmental quality and health benefits that include improving air pollution, attenuating noise, controlling the wind, providing erosion control, and moderating temperatures

## Agglomeration

The height of structures is additionally an issue of agglomeration in business district. Urban agglomeration hinges on the proximity of activities and tall buildings do just that. Clustering tall buildings fosters urban synergy for diverse activities and specialized services.

# PLACE: SHANGHAI

The world map

China

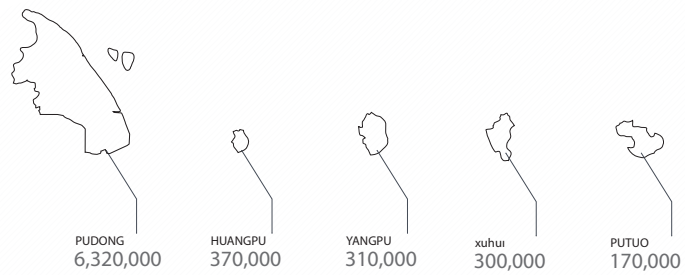

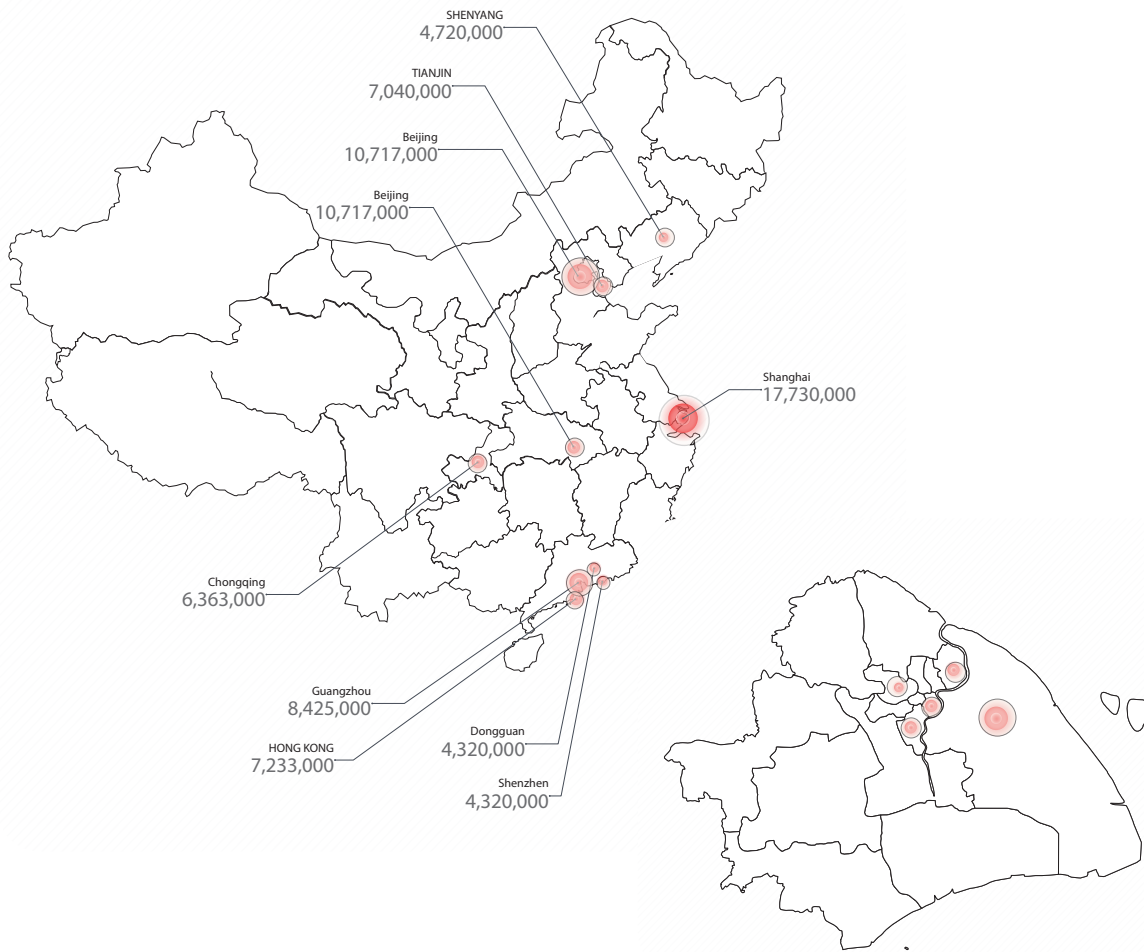

Shanghai

Pudong

The coastal city of Shanghai, is located at the mouth of the Yangtze River, and through years of even world has changed in many ways, the city kept its place in one of the major important cities overall the world. From the times that it was

just a fisherman town to nowadays; faced many urban transformations, evolving and growing; currently holding the largest urban population in China and one of the most active cities in the world in constructing tall buildings.

---

# PLACE: SHANGHAI

Locating on the southern estuary of the Yangtze River, with the Huangpu River flowing through it, the city has always been having a great importance, even in the back of times when it was just a fisherman town.

Today with the population of 24.89 million as of 2021, keeps its place in of the world's is the most populous urban area in China and the most populous city proper in the world, one of the world's major centers for finance, business and economics, research, education, science and technology, manufacturing, tourism, culture, dining, art, fashion, sports, and transportation.

As many of the major standing cities with great numbers of population, Shanghai was deeply invested on high rise buildings. Overall, in the first two decades of the 21st Century, Shanghai will add 156 skyscrapers to the 69 skyscrapers it built previously.

As indicated previously the trend for living high rise can be supported by many different objectives; environmental aspects, population, prestige, appearance, land prices... On the other hand it is also true that with the urgent need of growth on cities can give birth to some quick unconsiderate solutions which as can be seen from some newly built cities in China have already turned into ghost cities as people do not want to move there even though the residential high-rise building units have been bought by speculative investors.

These are ominous indications that the construction glut has resulted in a housing bubble that will likely burst in the near future. Taking into consideration the transformation Shanghai has been through in recent years, the rapid population increases, rapid change on city silhouette and people's lives; it is crucial to have a second look towards the life on vertical.

# ANALYSIS

Many Asian cities are experiencing a population explosion and economic expansion, the unprecedentedly rapid rise of the urban scale in the early 21st century is leading to the creation of megacities with populations exceeding 20 million.

With an exploding population migrating from rural areas and small towns to large cities, particularly in Asia, residential and commercial/mercantile accommodation problems continue to magnify. The future of these cities lies in the inevitable construction of high-rises unless an alternate solution is found for creating architectural spaces, and efficient infrastructures.

On this point, to analyse the conflicts that are being faced on the existing design of high rise for housing, understanding the needs of the context and the residents becomes a crucial point for the study of new ways of living vertical.

## Ming Period, Walled City of Shanghai (1368 to 1644)

the typical structure of Chinese city features

low-rise traditional courtyard houses

market & street relations

Figure 8: A view inside Shanghai walled city before the treat port time showing the typical structure of Chinese city with low-rise traditional courtyard houses, market, and street. Outside the wall were trading ports of this market

Shanghai is strategically positioned at the T-shaped junction of two major economic belts in China: the Eastern coast and the Yangtze River Valley. This advantageous location spurred the formation and growth of Shanghai, which quickly developed into a major financial centre within a century after the early 1840s when it was a small town. Since the walled city of Shanghai, to date,

the city has already experienced three eras of urbanisation, each stage exhibiting distinct characteristics in terms of population, industry, role in national and regional financial systems, urban expansion and so on. These complex and rich historical processes have left their mark on the city; each one morphing and transforming the urban fabric of Shanghai.

# SHANGHAI THROUGH HISTORY

The traditional planning of a Chinese city:

The north-south orientation for maximum exposure to sunlight

Figure 9: A plan of Shanghai walled city showing the basic traditional planning of a Chinese city.

includes the north-south orientation for maximum exposure to sunlight, organic structure of houses and neighborhoods,

which had been built and added to the sides of two main east-west spines over time constituting organic city's morphology.

## Small Town to a Metropolis 1843–1949

Shanghai's first era of urbanisation in modern times began in the 1840s with the forced establishment of the British Settlement and the French Concession in the area.

By the 1920s–1930s (the so-called Golden Era of modern Shanghai), the city developed into the financial centre of the Far East.

When Shanghai opened up for development in 1843, the small town's territory was mainly made up of the area enclosed by its city walls and the wharf area along the Huangpu River.

The town existing at that time is today's Lao-Cheng-Xiang or the traditional town, nearly 2 km<sup>2</sup> in size.

The first foreign settlements were planned north of this town along the river, with the intention to separate foreign settlements from Chinese areas. Project area which is defined in today's Shanghai City is on the Pudong region; which is a horn on Huangpu river and under transformation & development in recent years.

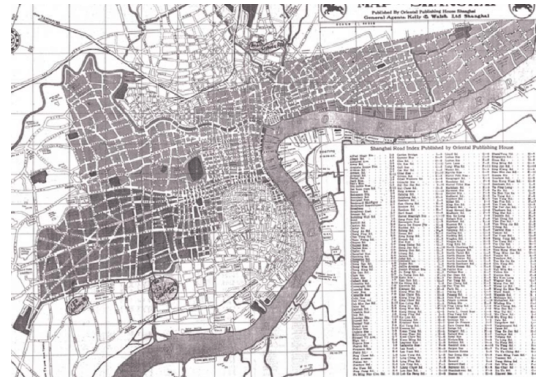

Figure 10: The first foreign settlements were planned north of this town along the river, with the intention to separate foreign settlements from Chinese areas. This separation formed the twin town structure of Shanghai half a century later.

# SHANGHAI THROUGH HISTORY

Figure 11: A map of Shanghai showing the spatial relationship between the Shanghai walled city and the British settlement where the Land Regulation was implemented

An official map of Shanghai by the Oriental Publishing House Press showing the occupation

Views of Pudong from the Bund before the massive development took place.

## A Primary Socialist Industrial City 1949-1990

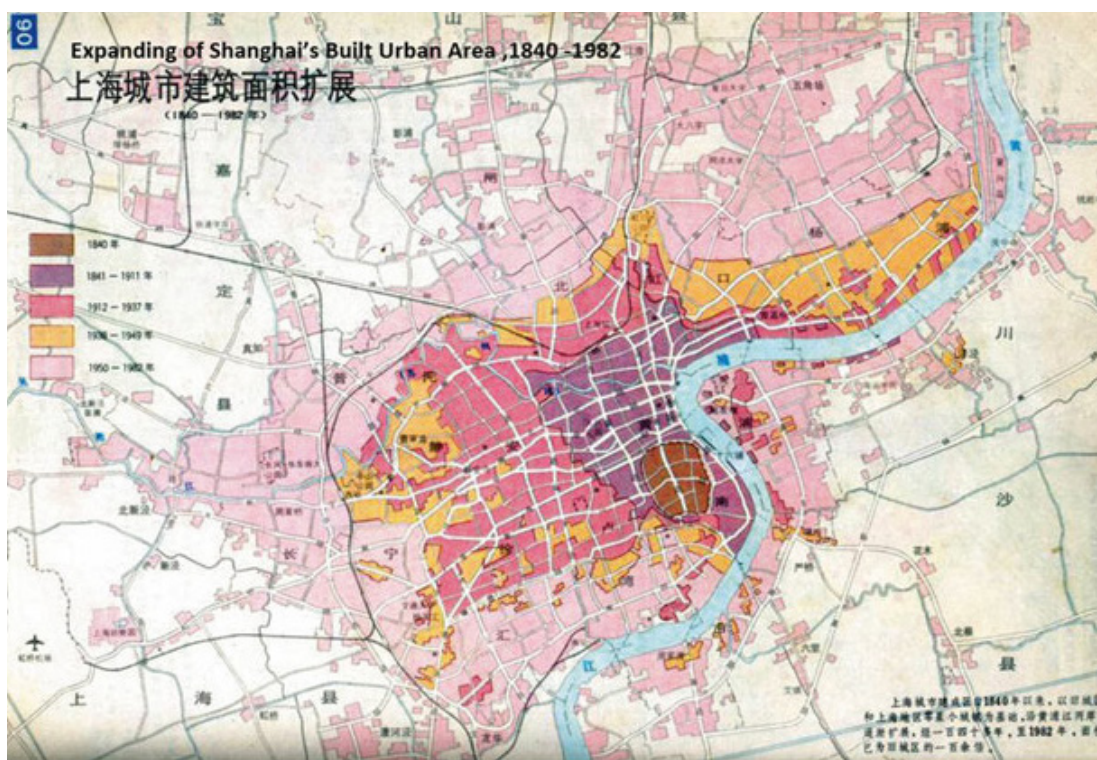

Figure 12 : Expanding of Shanghai's built urban area from 1840 to 1982

The second era of urbanisation happened after New China (the People's Republic of China) was founded in 1949. rebuilding the country's economy, developing the manu-

facturing and industrial sectors was highly prioritised. In response, Shanghai swiftly transformed from a financial centre into a comprehensive manufacturing hub.

# SHANGHAI THROUGH HISTORY

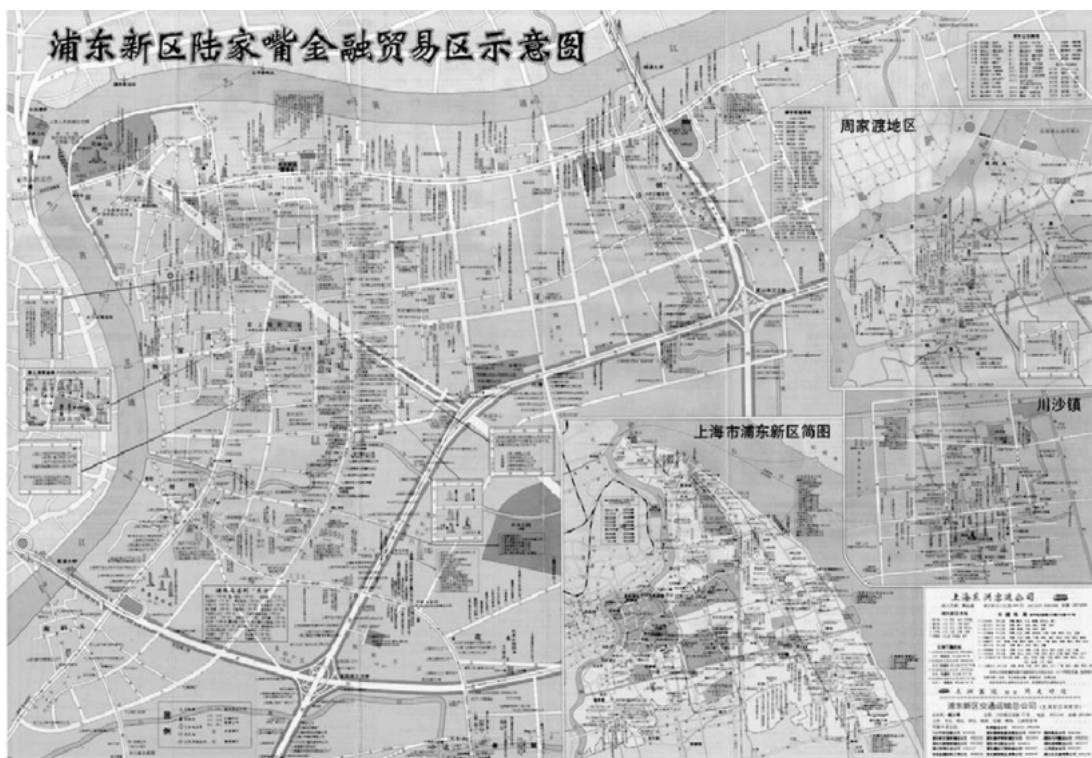

Figure 13: A map of Shanghai in 1994 after the first phase of massive road and underground infrastructure

From 1949 to the late 1970s when the Cultural Revolution ended, Shanghai's population doubled from 6 million (in the early 1950s) to about 12 million (in 1982).

Shanghai in 1994 after the first phase of massive road and underground infrastructure investment was put in place for the developers to build buildings according to the master plan.

## Urban Transformation after China Reform & Opening General Overview

Strictly speaking, these manufacturing districts could not be considered urban areas – they were just large plots of factories with workers' living quarters built beside.

They had a strong socialist character, but did not truly form city-like urban areas. As the living quarters included amenities such as kindergartens, primary schools and healthcare facilities that were all provided by state-owned work units.

At the early stage of the China Reform and Opening, from 1978 to 1990, development in the Pearl River Delta region centred on the new city of Shenzhen, which became the test-bed for the nation's reform and opening ideas, while Shanghai took the back seat in China's economic reform plan at that period.

At Shanghai during the ten some years, since new economic sectors had taken over the old manufacturing sectors, the new and old economic systems experienced much friction.

Although Shanghai's economic growth had always been strong, its rate of growth was lagging behind that of the Pearl River region at that time, so Shanghai's economic importance in the country fell. Consequently, during this period, there was no significant change in the urban framework of Shanghai.

As for physical urban development, contrary to Shanghai's contribution to the country, the Shanghai quality of life kept falling. Up till the early 1990s, Shanghai's average living space per capita, green space per capita, public

transport situation and other key indexes of living conditions ranked among the country's worst. It was also during this prolonged period of declining living conditions that Linong areas and other historical areas became extremely densely populated, giving such places a slum image.

The years between 1991–2010 China's open door policy forms the backdrop of Shanghai's third era of urbanisation, which took place in line with the larger context of China's urbanisation in this period. In 1991, Shanghai's urban development entered an era of great change. This is according to the Chinese central government's strategy and policy that 'with the development and opening of Shanghai Pudong as the spur, the cities along the Yangtze River will be further opened up, in order to shape Shanghai as one of the international economic, finance, and trade centres and thus bring along new leaps of regional economy in the Yangtze River Delta and the whole Yangtze River Valley', which led to the development and opening of Shanghai Pudong and its official launch in 1991. Shanghai's population has risen to 23 million in 2011, almost doubling in the past 30 years, while the built area of the city increased from 1,000 to 2,860 km<sup>2</sup>.

Shanghai thus underwent a fundamental change within the 10-year span of the 1990s. The rapid momentum of Shanghai's growth since Pudong Development began in 1991 has continued into the twenty-first century, with the Shanghai World EXPO in 2010, continuing to attract global attention

# SHANGHAI THROUGH HISTORY

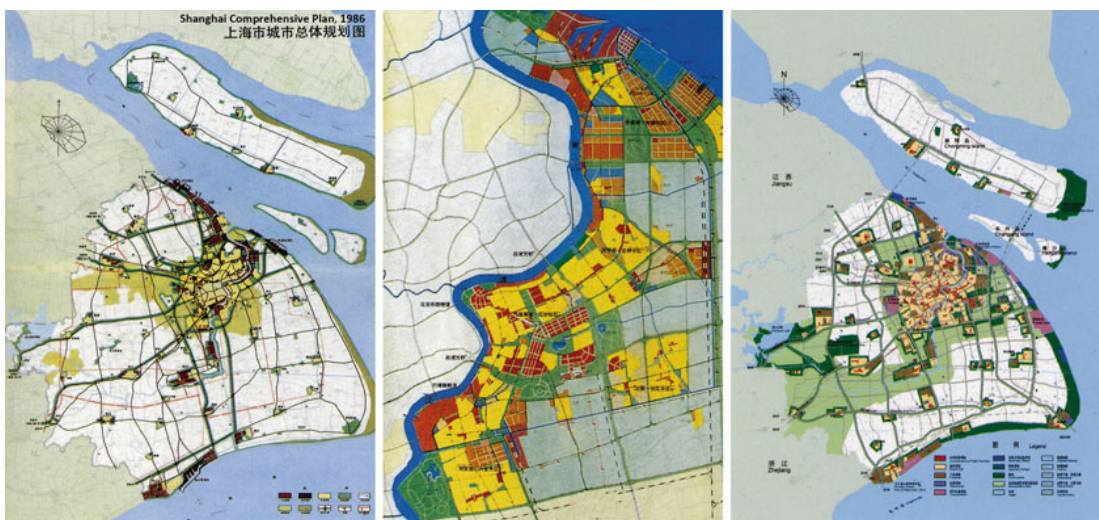

Figure 14: Left to right: Shanghai Comprehensive Plan, 1986; The Comprehensive Plan of Pudong New District, 1991, Shanghai Comprehensive Plan 1999–2020, 1999

On the one hand, this change brought about a rapid improvement in basic urban infrastructure and a substantial improvement in the living conditions of the public.

Shanghai's living space per capita rose from 6.9 m<sup>2</sup> in 1992 to 13.1 m<sup>2</sup> in 2002. On the other hand, such rapid development has also raised questions and criticism of various aspects of the city's history, culture and social problems.

The Comprehensive Plan of Pudong New District published in 1991 expanded and almost doubled Shanghai's urban territory across the Huangpu River. Crossing the river with several bridges and tunnels and plans for Lujiazui Central Business District (CBD), Huamu Civic Centre, manufacturing

and industrial zones, Century Avenue, major iconic public buildings and a series of building initiatives signalled Pudong Development in full force. A new Pudong presented itself before everyone at the turn of the century, after 10 years of rapid development under the slogan 'A new look every year, an astonishing change every three years'. This was also the most evident symbol of Shanghai's success in the 1990s.

# SHANGHAI THROUGH HISTORY

A large proportion of Pudong New Area has relatively low urban vitality, apart from the Lujiazui and its surrounding areas. Pudong New Area is affected by modern zoning plan, which forms a monotonous built environment.

Since Pudong was approved as a national-level new area in 1990s, it was divided into five zones for specialized industries. In 2000s, Sanlin and Chuansha were added as two additional specialized zones aiming to develop World Expo and logistic industry, respectively.

Zoning plan allows these specialized zones to preferentially supply large-scale industrial land in suburb, which facilitates to accommodate enterprises and factories.

Stimulated by this industry-oriented land development strategy, local authorities make efforts to establish industrial parks and transport network.

Meanwhile, zoning plan tends to feature grid-pattern road network composed of dense urban expressways, with sparse outspread paths. Under the circumstance, many industrial parks and neighboring residential communities are divided into large number of independent large-scale closed blocks with an enterprise or a residential community, forming regular layouts. The plan is similar to American's Euclidean zoning that is featured by the segregation of urban land into independent spatial units.

It therefore results in absent road junctions and 'human touch', leading to severe road vacuums.

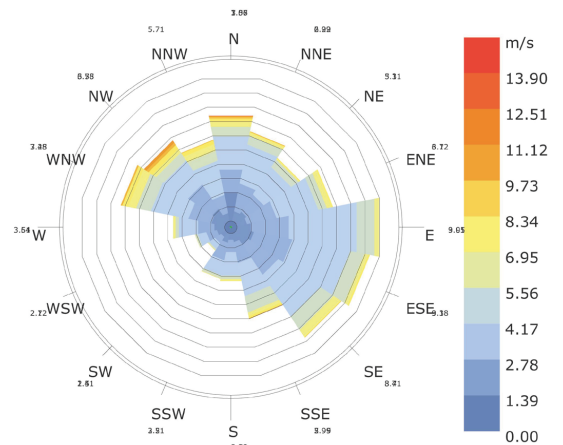

Consequently, monotype land use, regular large-scale blocks, and road vacuums render many sub-districts of Pudong as hardest-hit areas for low urban vitality.

## The Traditional Chinese Town: Shanghai Lao- Cheng- Xiang

*The form and organisation of presentday streets evolved from a canal network. Its clear hierarchy yet organic web-like pattern of street- lane-path-end leads from the city's public areas to the private realm as it weaves through densely packed low-rise buildings. The old areas generally have low-quality,*

*slum-like living conditions. Due to the high level of subdivision within units, many dwellings lack basic amenities such as toilets for every unit. Shared cooking and washing spaces are common. There is liberal use of the already narrow public streets due to overly cramped private spaces.*

Figure 17: The living conditions of Lao-Cheng- Xiang today, along the stretch from Penglai Road to Wangyun Road View of a typical old street

# ANALYSIS URBAN PATTERNS

## Lilong Typology: Center of Shanghai

Figure 20: Rooftop scene of a Linong area. This widespread homogenous rooftop image is one of the most typical urbanscapes in central modern Shanghai. It is created by the repetition of a basic housing unit, a modified traditional Chinese town house, to form rows

The Linong (also called Lilong or Longtang) typology is a well-developed urban housing typology at Shanghai in China's modern history. As a response to rapid urbanisation, a massive population influx (creating the need to accommodate higher densities) and a shift to urban lifestyles, the Linong typology, evolved from the 1860s to the 1930s, combined traditional Chinese dwellings within an overall Western structure. Linongs are generally 2–3 storeys high, with a clear hierarchy of spaces from public to private.

Linongs were originally designed to house the middle class. However, due to certain historical factors, it gained a slum-like image as the units became subdivided and overcrowded.

With a clear hierarchy of spaces from public to private

The street entrance to the Linong, which leads directly into the main lane, is usually integrated with the street front consisting of an outer layer of shops.

# ANALYSIS URBAN PATTERNS

Figure 21: Photos reflect typical living conditions in the late 1980s Linong housing. The lanes formed safe play spaces for children and good daily gathering spaces for all, enhancing the sense of community. These would have been familiar scenes to most Shanghainese. Due to certain historical factors such as war causing the population to swell and the unreasonable density and conditions following New China's establishment, this kind of housing gained a slum-like image as the units became subdivided and overcrowded

Figure 22: The street entrance to the Linong, which leads directly into the main lane, is usually integrated with the street front consisting of an outer layer of shops.

## The Bund Area: Financial Symbol of Far East

Figure 23: Aerial views of the Bund Area. Although not considered high-rise today, this area is still densely packed.

The Bund Area was the financial engine of Asia during Shanghai's golden era of the 1920s–1930s, leading the rest of East Asia's financial development. Urban life and financial activity were interwoven, making this urban spatial model very adaptable, and this was planned as such. From the 1990s onwards, the Bund Area has faced a fourth wave of urban renewal, with many transformations and new construction projects. The biggest challenge is how to retain the historical characteristics of this area, enhance its urban spatial quality and strengthen its legacy of the Asian financial engine.

Figure 24: Aerial views of the Bund Area. Although not considered high-rise today, this area is still densely packed.

# ANALYSIS

## URBAN PATTERNS

The city witnessed three major stages of urban transformation before 1991's rapid development.

- the 1840s to the late nineteenth century: typical colonial style 2–3 storey buildings, placed in the middle of the plot, surrounded by gardens and lawns enclosed by fence walls;

- the late nineteenth century to the early twentieth century: a fully typical European urbanism in a modern Chinese city was achieved – a grid street network, with many buildings rebuilt to 4–6 storeys high, leaving the colonial typology for one that filled the plot right up to the street, forming a continuous street wall, and very European facades;

- the 1920s–1930s: some buildings were renovated or rebuilt, with many becoming 8 storeys and up, although the building and street relationship and the street grid system were not altered

Figure 25: The 1980s back view of the Bund. The opposite bank in the background is the location of today's Pudong Lujiazui CBD; the Bund in the beginning of the twenty-first century. The highway ramp seen here was demolished after the underground highway was constructed, prior to the 2010 Shanghai EXPO (Source: Shanghai Planning and Land Resources Administration Bureau)

## Lujiazui Central Business District (CBD)

If the Bund is the iconic representation of the financial centre of the Far East during modern Shanghai's golden era, then the Lujiazui CBD's skyline, as seen from the Bund, can be said to be Shanghai's symbol of progress towards becoming a global financial centre in the twenty-first century. Since 1991, when China's central government announced the development and opening of Shanghai Pudong, until the beginning of the twenty-first century, this area grew from a single Oriental Pearl TV Tower to a whole new CBD within a decade. It represents Shanghai city rebuilding its image as a financial hub, and it has greatly helped the city attract and retain many international financial institutions.

The typical urban pattern of Lujiazui is towers placed in large urban blocks with an abundance of open space surrounding each tower, and each block is surrounded by wide traffic roads which lead to main entrance plaza or underground parking of each tower. These towers usually contain commercial office spaces or major shopping complexes. Some footbridges have been added in recent years to form a second street level for pedestrians, due to the high traffic volume on the ground.

## URBAN PATTERNS

### Civic Centre Complex: Huamu Civic Centre Area

The Huamu Civic Centre Area was publicly funded to drive Pudong's urban development deeper into the rest of the land away from the Huangpu River. It has been quite successful in achieving this aim as planned in the beginning of the 1990s, but not without some criticism on urban pattern.

At the heart of the civic centre is a large open square. It is surrounded by important civic buildings mainly designed as landmarks and used as a visual end to the grand axis of Century Avenue that started in Lujiazui area.

This has encouraged the widespread development of luxury residential apartments around it. Therefore, this has become a high-class residential area.

Large open square in the middle of civic centre.

Good quality public space leads the other building complexes to appear around.

Large open square in the middle of civic centre

## Luxury Residential Area: Huamu Residential Area

Close to the civic centre and Century Park is a concentration of high-class luxury residences in Huamu. Much of the residential areas are targeted at the upper-class population from the Lujiazui CBD, Jinqiao and Zhangjiang's white-collared workers and foreign expatriates.

This case study also highlights another situation that has arisen: huge commercial complexes have become very important to formation and success of new residential districts.

The luxury residential buildings have a large footprint, but the built density is comparatively lower than the city centre. The housing architecture often stresses variety with several typologies and designs, such as separated villas, high-class condominiums, mid-rise and high-rise. This case study also highlights another situation that has arisen: huge commercial complexes have become very important to formation and success of new residential districts.

Figure 27: The environment within a typical residential development. Within these large compounds, there is much attention placed on provision of play areas and high-quality landscaping

## URBAN PATTERNS

### Jinqiao Manufacturing Zone

Jinqiao manufacturing zone is located in the central part of Pudong. There are industrial manufacturing, trade operations, financial services and other functions, such as a modern industrial park, lifestyle services centre and customs management. Since the district was developed independently, it lacks integration with the surrounding urban areas in terms of traffic, pedestrian movement and mix of uses and so on. The typical factories and offices are low-rise buildings sitting in the middle of gated compounds, creating street images made up of the walls enclosing the compounds and guardhouses at the entrances.

manufacturing zone is located in the central part of Pudong

it lacks integration with the surrounding urban areas in terms of traffic, pedestrian movement and mix of uses

### Zhangjiang High-Tech Park

Residential and recreational functions are not well-planned and built in the area; hence, most of people working in the high-tech part do not live nearby their workplaces, resulting in an estimated 180,000 people flooding in and out of Zhangjiang High-Tech Park everyday. Compared to the Jinqiao Manufacturing Zone, Zhangjiang has more public green; however, there is still a lack of public urban life. The urbanscape is still made up of the same typology of buildings seated in the middle of large gated compounds, with a lot of open space left for landscaping, be it residential, factories, offices, schools or other amenities.

# ARCHITECTURE

The key to understanding how to reinterpret the functional role of the courtyard in a tall building was to study and deeply comprehend for which aim it has been used from the early dates in Chinese history, until the contemporary way of life of young Chinese. Use of the courtyard in traditional ways was in a private. Being surrounded with different functions, or in specific examples different family houses, created a protected place for people to gather such as for families that children can play, the market place and housings that people can meet, have free spaces to have physical exercises and so on.

With the demographic analysis around the site, and the approximated inhabitant user profiles of the tall building, the idea of living together in a tall building is generated around of contemporary 'courtyard' became 'loggia's on the 4 corners of the building, with a goal to keep its traditions on the society as being a social condenser, a place that people can spend quality time, protected and used daily in which people can interact, as they used to interact with in the traditional courtyard.

## Understanding Daily Life & Space Needs

The aim with this tall building is to introduce a new concept on living in the 'tall building'. The analysis that is made on the other tall buildings in Shanghai, shows that the way of life in these areas are all other areas, are switched on and off according to the time of day or the day of the week. People living these places defining themselves as dormitories around which the presence of places that host other types of activities is rare and where the users, or rather the inhabitants, do not find places and ways to interact, interrupting those social movements that give life to a community.

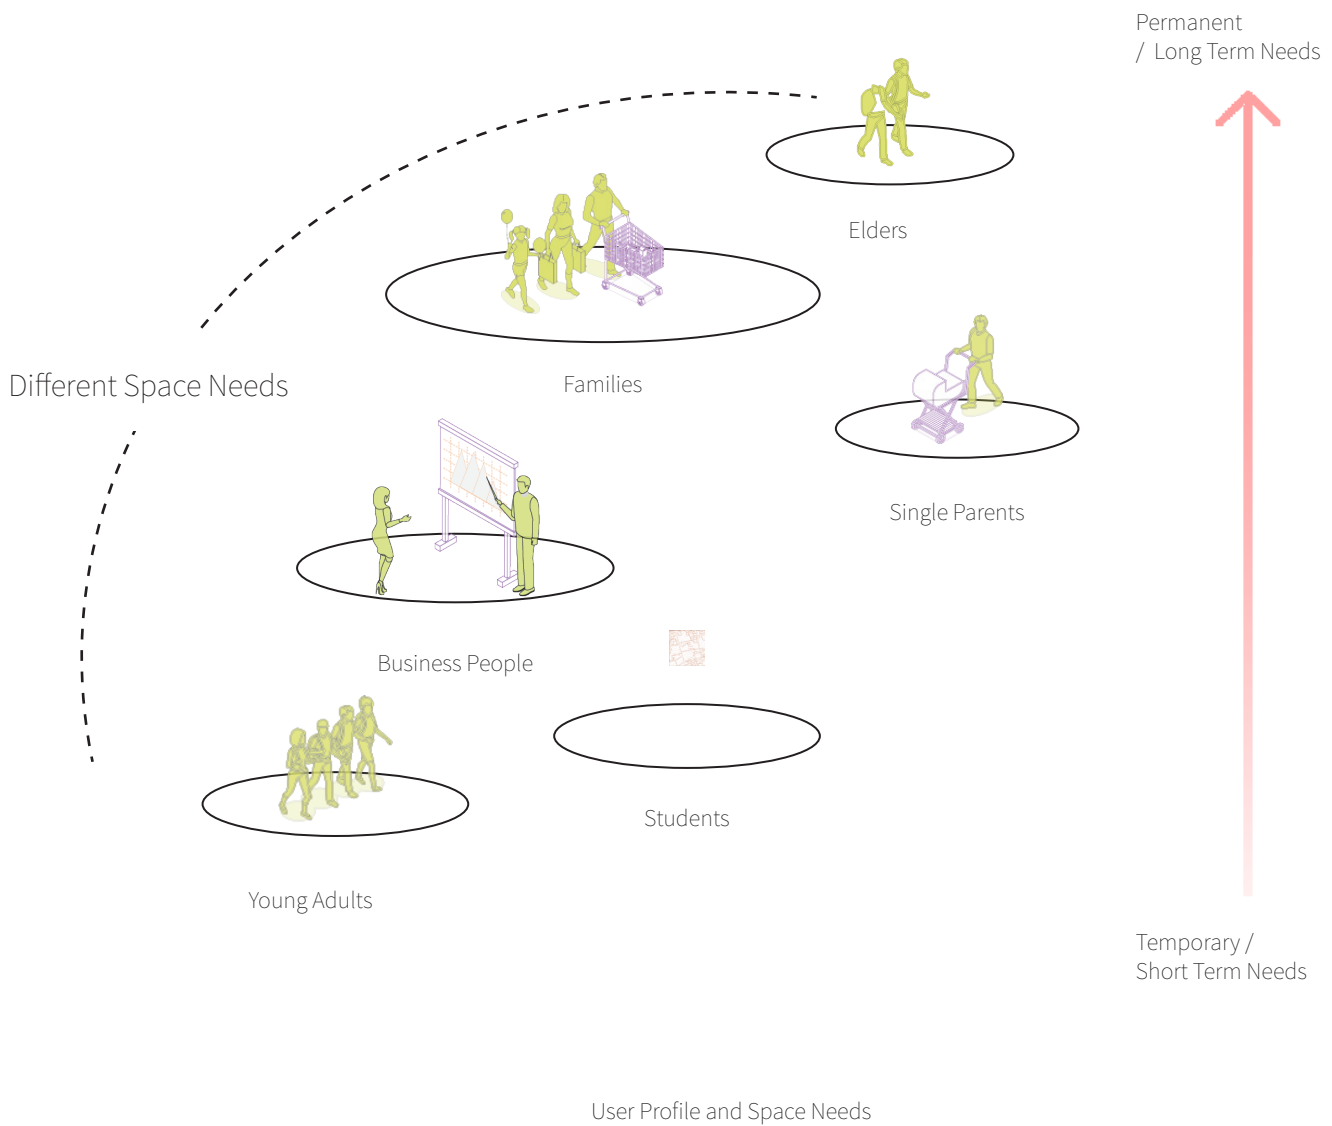

It is essential to the tower is the quality of life, of the spaces and interactions that, this time, take place inside a tower. On this, we would like to discuss three fundamental points that we believe to be among the major contributors to the theme: the psychological effects of living vertically, the monotonous repetition of floors that leads to the disorienting indistinguishability of spaces, the discordance between the programmatic layout and the reality of the users. (i.e. towers created for an indistinct "user X" far from the reality of the Shanghai inhabitants and their needs).

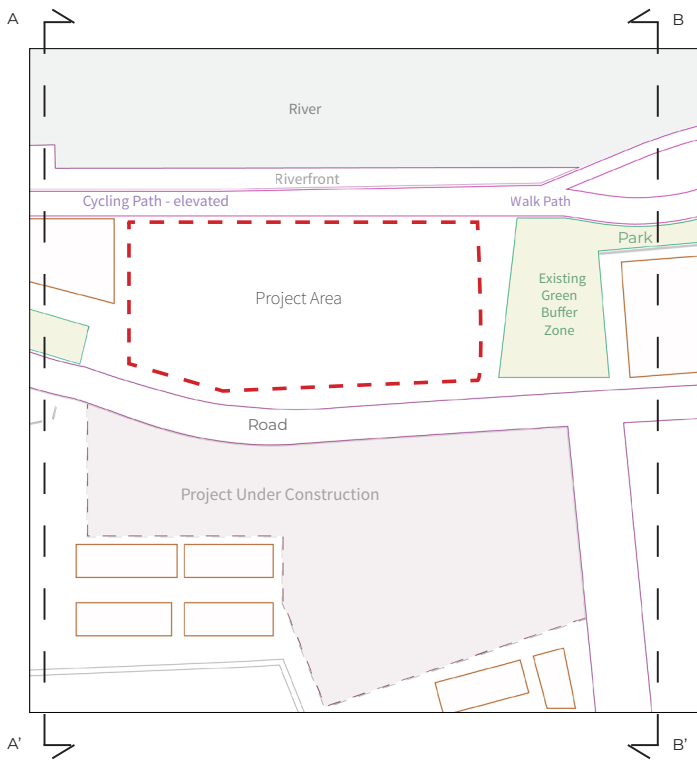

So why not work on this critical architectural typology with the intention of finding new solutions, given that it will not abandon the "Port of the Orient" so quickly, but instead is becoming increasingly representative of it.

The approach we propose is to develop a tower that adapts to the real needs of those who use it, that is shaped according to the reality of the social structure of the community to which it will belong, and that creates a new way of contemplating the relationship between the tower and the city; blurring through the podium towards the level of the public street.

# ARCHITECTURE USERS & SPACE NEEDS

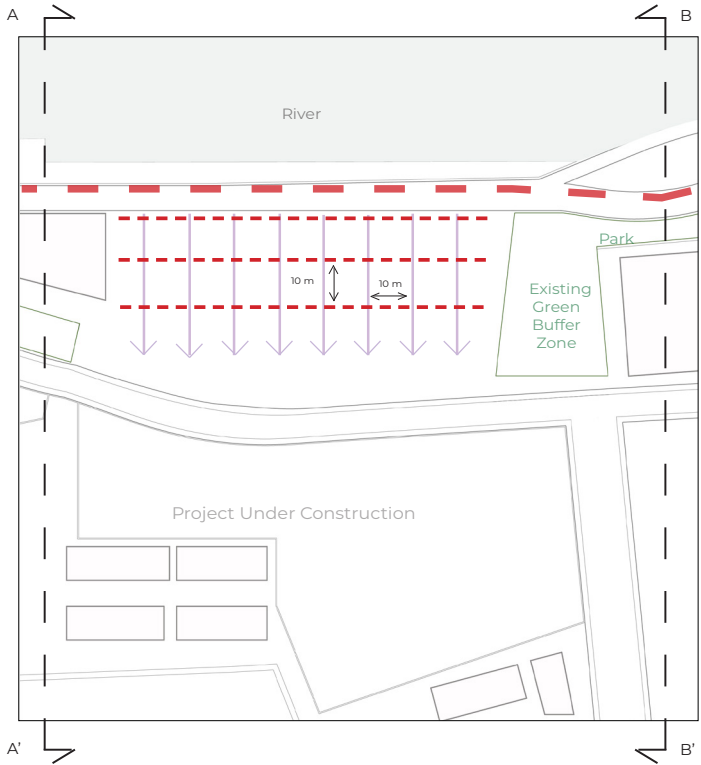

Understanding the existing conditions of the context was a crucial step to have proper approach on design decisions such as footprint, height, and defining the relationship with ground.

The pedestrian flow is following the riverfront, further through the west meeting with the green axis. While

### Solar Radiation Analysis | LadyBug

Climate visualizations in 2D and 3D are included to facilitate decision-making early on in the design process. In addition to solar radiation studies, view analyses, and sunlight hours models, Ladybug also assists design stages with the evaluation of initial design options. A high degree of customization is possible with integration with visual programming environments, which provides instant feedback on design changes and allows instant feedback on modifications.

The results of the Ladybug analysis show that the building complex has overheated surfaces at the top of the building, while the radiation levels on the facades vary

depending on the orientation.

In the analysis, it was decided to pay attention to the difference between the data with the second skin facade and the one without.

Due to reduce the solar radiation on the building's inner space a second skin with an opaque pattern has been designed.

All this opaque panel are made of photovoltaic panels with the double aim of, take advantage from the sun radiation generating electrical energy and in the meanwhile create shadow to the building.

- HEAT ISLAND REDUCTION.....UP TO 2 POINTS
- OPTIMIZE ENERGY PERFORMANCE.....UP TO 2 POINTS
- INNOVATIVE PRODUCT.....UP TO 1 POINTS

\* The energy production figure mentioned herein has been calculated according to the number of other external projects that have not been taking into account. These factors might result in a reduction in energy production. In addition, other external losses due to BIPV are not included from these calculations. The calculation has been done using PVGIS and PVWatts.

\*\* Calculated with average efficient light bulbs of 10W

## RESULTS WEST SIDE

CRYSTALLINE PV

3065 MQ

### ELECTRICITY GENERATED IN 35 YEARS

8,235,894 kWh \*

### TOTAL LIGHTING POINTS OPERATING 4 HOURS PER DAY

16,160 Lights \*\*

### AVOIDED CO<sub>2</sub> EMISSIONS IN 35 YEARS

6,292 t CO<sub>2</sub>

The CO<sub>2</sub> emissions avoided have been calculated with the customer energy mix value of the selected country.

### BARRELS OF OIL SAVED IN 35 YEARS

4,846 Barrels

### LITERS OF OIL SAVED IN 35 YEARS

770,568 liters

### ELECTRIC CAR MILEAGE IN 35 YEARS THANKS TO THE ENERGY GENERATED

47,356,392 km

### TREES PLANTED IN THE AMAZON THANKS TO THE INSTALLATION

3,065 Trees

Thanks to our innovative eCO<sub>2</sub> metered surface, the energy response (meter) of photovoltaic solar glass will be like that of a tree in the Amazon.

### BY INSTALLING OUR SOLAR PV GLASS YOU CAN REACH UP TO 8 LEED POINTS

RENEWABLE ENERGY PRODUCTION ON-SITE.....UP TO 3 POINTS

HEAT ISLAND REDUCTION.....UP TO 2 POINTS

OPTIMIZE ENERGY PERFORMANCE.....UP TO 2 POINTS

INNOVATIVE PRODUCT.....UP TO 1 POINTS

\* The energy production is just an estimation where factors like surrounding obstacles, self-shading or other external impacts have not been taken into account. These factors might lead to a reduction in energy production. In addition, other potential losses due to BOS are also excluded from these calculations. The calculation has been done using PVGIS and PVWATTS.

\*\* Calculated with energy efficient light bulbs of 12W.

# STRUCTURE COMPOSITION

## Understanding Daily Life & Space Needs

**Two cores:** To give more stability to the tower especially when subjected to the strong horizontal thrust of the strong winds caused by the seasonal monsoons. Having two cores in which to place the vertical road system allows us to have an efficient escape route system by ensuring two separate escape columns.

**Columns:** We chose to use no less than 28 columns running the full height of the tower; from the foundations to the top. This was to be able to support all the loads the floors are subjected to without the need for a massive structure that would also take a central role in the overall external appearance of the tower.

**Metal sheet:** The chosen construction system is that of trapezoidal sheet metal floors. This was the preferred system from the outset due to the high lightness and mechanical strength of the material. The ceilings are then completed in different variants so that adoc ceiling packages can be created according to the functional area served.

**Wind:** Wind is a key element in the design of tall buildings in Shanghai; not only because of the natural predisposition of this architectural type to suffer more than others from the force of the wind. Seasonal typhoons are a major issue, so we have inserted stiffening planes along the tower to hold the structure together. These floors will also serve as a support surface for the MEP system.

This is to get to the heart of what we wanted to achieve in developing our structure: a tower element that is not just a skeleton but serves as a solid base from which to start, as with the static nature of the type of tower chosen, to be able to feed the functional complexity that we want to host within our spaces.

## Sizing Structural Elements

In this chapter of the report we will focus on the pre-dimensioning, analysis and verification of the most stressed structural elements of the tower.

The structural analysis is mainly divided into three parts where we focused on the structural elements of a typical floor, plus the structural elements of two “Loggia” floors: the floor of the “Courtyard” space and the green roof of the podium.

In this way we were able to dimension the structural elements more carefully, reinforcing them where the increased forces acting on the structure made it necessary.

## 2.2 Loggia primary beam calculation

This type of boundary beam supports the tower-type floor. In this case it has been dimensioned and verified under the forces of the worst mechanical condition to which it can be subjected.

$$q = (12,85 \cdot 5) + (11,73 \cdot 5) = 123 \text{ kN}$$

$$P = V_{e,d} = 123 \text{ kN}$$

# LOGGIA

## 08. BIM

Building Information Modeling (BIM) is an intelligent 3D model-based process that gives architecture, engineering, and construction professionals the insight and tools to more efficiently plan, design and construct.

For the architects BIM is a possibility to make better design decisions, improve building performance, and collaborate more effectively throughout the project lifecycle.

Throughout the project it creates conditions to come along with real time inputs on the design process that give a boost in making decisions and finalizing the building idea.

There are 8 dimensions of BIM:

1D: Scratch point

2D: Vector

3D: Shape

4D: Time

5D: Cost

6D: Performance

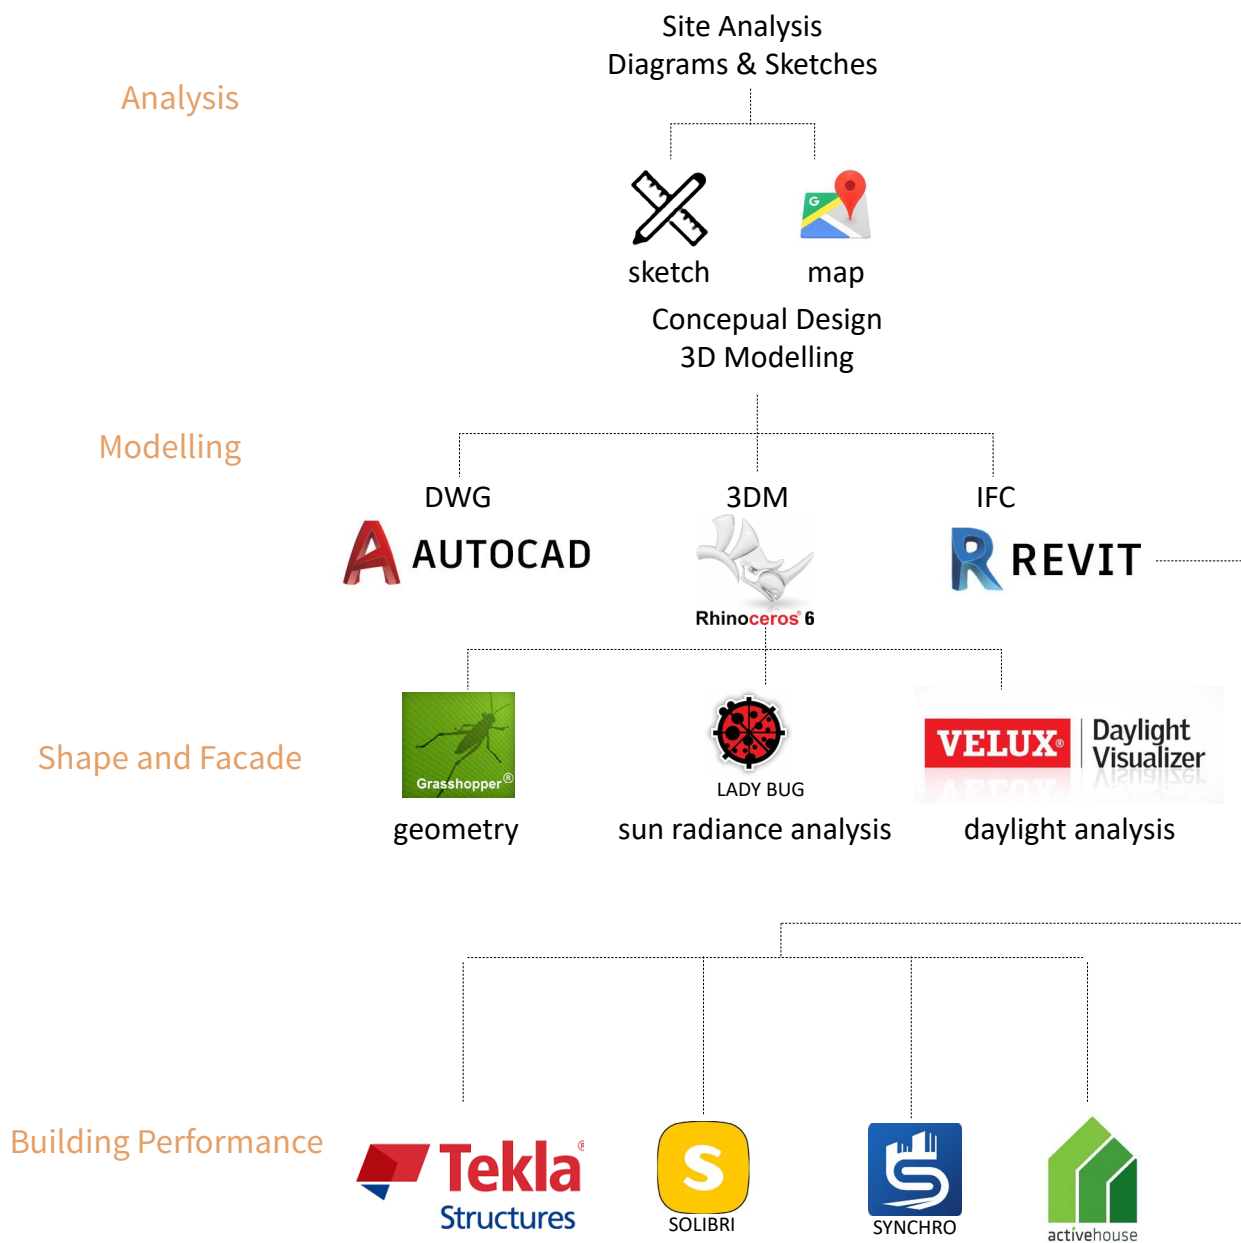

7D: Sustainability

8D: Safety

On this project 6 dimensions were applied, starting from concept development and research phase to site simulation, there are constant information flow between each step of development.

Constructable dimensions is the phase that aims to achieve the design of the performative and yet also aesthetically complex skin, and the project development focuses on the parametric and constructability of the tower and facade geometry. Moving on the detailed modeling in Revit give an estimate type and quantity of the materials that was used and helps to understand the potential cost which will be clearly seen in further pages.

# BIM STRATEGY

The BIM's Level of Development (LOD) defines how the 3D geometry of the building model can achieve different levels of refinement, is used as a measure of the service level required.

There are 3 levels of development were conformed to the project and can be followed on the scheme.

LOD (100) Concept design; The model element may be graphically represented in the model with a symbol or other generic representation.

LOD (200) Approximate geometry; The model element is represented in the model as a generic system. With approximate quantities, size, shape,

LOD (300) Detailed design; specific assemblies accurate in terms of quantities, size, shape, location and orientation. used for analysis of defined systems and general performance objectives.

LOD (400) Fabrication:

The model element is graphically represented as a specific system. With accurate definition and detailing in dimension and installation. Here models are suited for estimating as well as construction coordination for clash detection scheduling and visualization.

# BIM STRATEGY

Skin generating

LOD 100: Concept Analysis.

On this phase site analysis, design process diagrams and sketches were made. It helped to define an idea and to clarify the possibility of the building to exist on a chosen site. Modeling.

LOD 200: Analysis and Design

More complex and in deep analysis of the site, location, building form. Furthermore, the softwares on which design could be made were assigned. Rhino and Grasshopper, 3D model and complex form of the second facade. Autodesk Revit, BIM software to design a building and structure and its components in 3D, annotate the model with 2D drafting elements, and access building information from the building model's database.

LOD 300: , Using the Grasshopper plugin

Ladybug to make solar radiation and sun path analysis of the building and land. VELUX daylight visualizer helped to understand and analyze conditions of the daylight inside the building complex. In this phase more detailed design process is held by using Revit.

The final result of this stage is a well detailed model with a precise geometry.

LOD 400: Is used to monitoring the construction of the building and its performance.

For the structures Tekla softwares were applied, it gave the idea of the connections and detailed structure performances. Besides, Revit data facilitates the performance of Active House that is a worldwide quality stamp for comfortable and sustainable buildings. Pachyderm Acoustic Performance helped to develop the theater hall and to get there an efficient performing values.

### Project

Active House

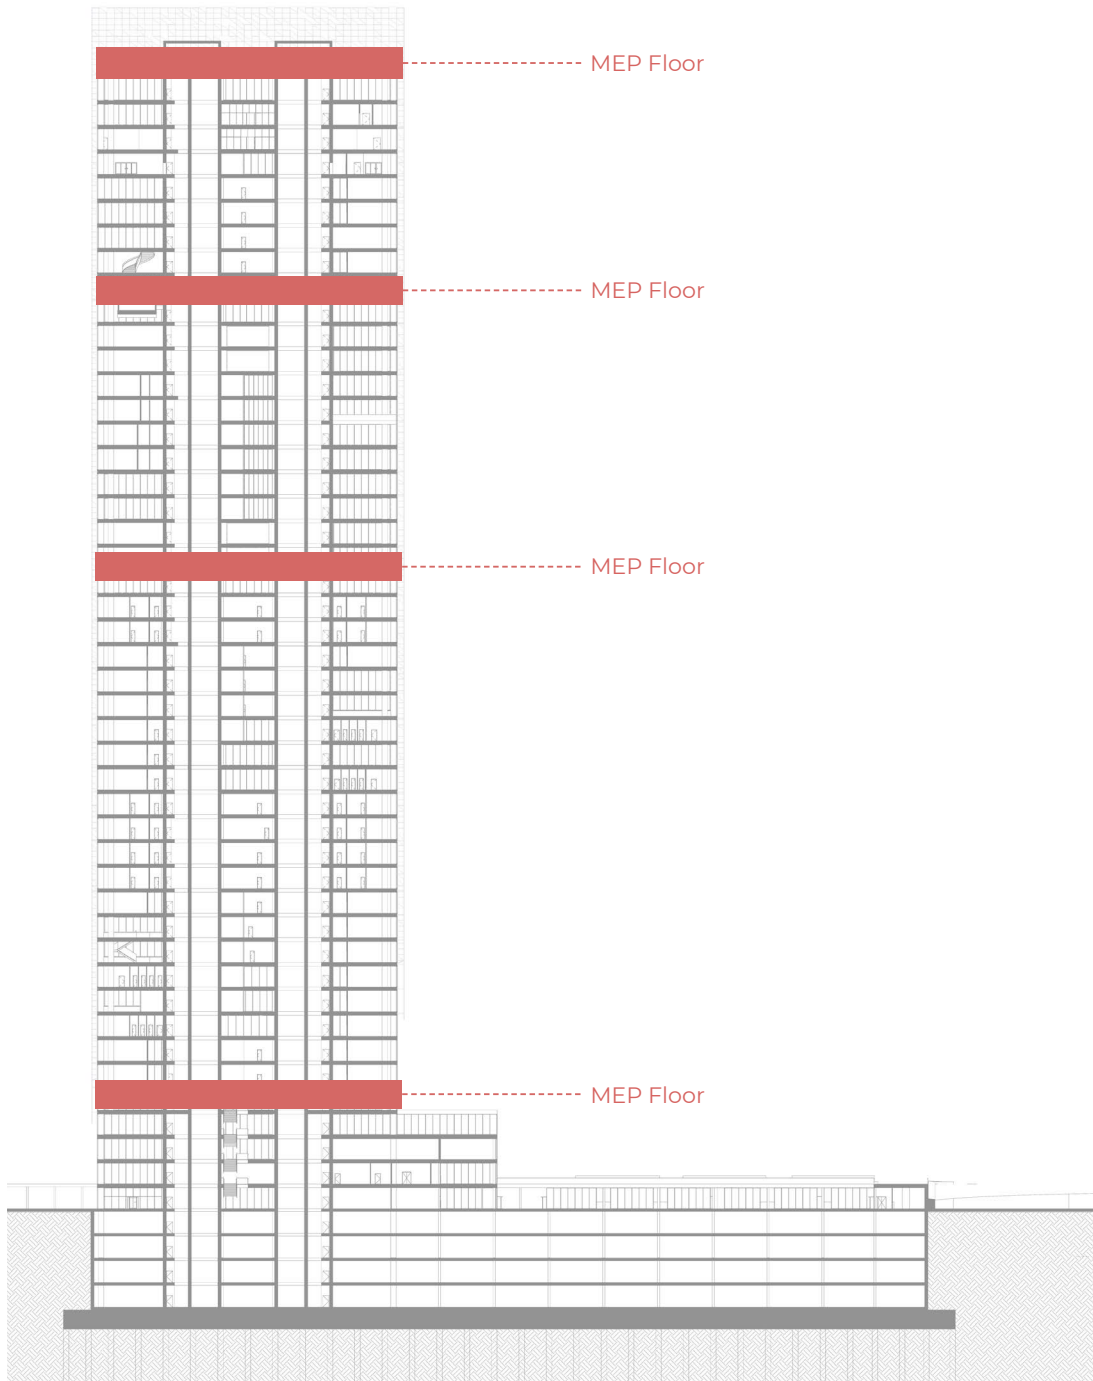

# 09. BUILDING SERVICES

The complex has one underground floor where all the technical rooms for climatization, storage, machinery needed for complete and successful work of the buildings are located. The floor is -4.5 meters below the marked 0, that is, the carriageway of the city. Also on this floor, there is a parking lot, which is connected with each part of the complex, that allows achieving excellent distribution of the flow of visitors, employees, cars.

Majority of the services are distributed in the basement with the exception of a few. The water tank for rainwater storage, Domestic use, and Fire fighting are also located in the basement.

# SERVICE ORGANIZATION

# WATER SUPPLY SYSTEM

Most buildings' water supply systems combine three types of systems: direct supply, indirect supply, and sump and pump supply. Fresh water is delivered directly from the public water mains to lower-floor residences by hydraulic pressure within the mains in the direct delivery system.

A water pump is used in the indirect supply system to pull water from the ground-level storage tank, and fresh water drawn into the rooftop water tank is then carried to each household through a network of sub-mains.

Water is conveyed to the receiving end of the sump and pump supply system by attaching a pressure pump to the supply: a fire main is an example of this. Water pumps, risers, storage tanks, automated float switches, and sub-mains are all vital aspects of a water supply system that should be examined and maintained on a regular basis. For quality control, all water storage tanks should be sanitized on a regular basis.

Drainage distribution

# DRAINAGE SYSTEM

Rain-water pipe systems and sewage pipe systems are two types of drainage systems. Drain pipes, traps, and manholes are all essential components of a drainage system. Drain pipes should never be connected incorrectly, for example, sewage from sinks should never be poured into a rain-water pipe. Drainage outlets should be kept clean or equipped with gratings to prevent trash from clogging the pipes. All drain pipes, including soil, waste, ventilating, and subterranean drain pipes, should be kept in good operating order and free of faults. All such pipelines should be inspected on a regular basis, and any leaks, blockages, or faults should be addressed right away.

Electrical distribution

# ELETTRICAL SYTEM

In the human body, the electrical system is comparable to the neurological system. It provides power to various portions of the building and aids in the control and communication systems.

The transformer, power distribution panels, light fixtures, telephones, and security devices are all examples of primary electrical assemblies. Different aspects of the electrical system are depicted in the images to the right.

#### Attributes

Some of the electrical system's characteristics are listed below.

Because mechanical equipment requires a lot of power and control, the electrical system and the mechanical system are inextricably linked. The electrical system is mostly inaccessible, with the exception of light fixtures,

power receptacles, and panel boards. As a result, the inaccessible elements' estimated useful service life (such as wiring) is frequently planned to be throughout the life of the structure or for very extended periods of time.

Periodic inspection, maintenance, and renewals are required for accessible components. Many of the assets are considered long- or medium-term investments.

Because the assets are sturdy and do not require much maintenance, the maintenance-to-replacement ratio (MRR) is often low.

#### Surface water based heat exchange system

To utilize the presence of Huangpu River in the vicinity of the project, a Surface water-based heat exchange system has been implemented in the project. The core idea is that surface water has always a temperature difference, this difference can be utilized sustainability to exchange the heat from the building.

To better define the services the Building has been divided into blocks. These core are served by the system throughout the shafts, these are they connected to the basement where the majority of the HVAC equipment are kept.

An Open Water Heat Pump system works by recovering the solar energy stored naturally in river water or open water. The water then passes through heat pumps to yield its low-grade heat before being returned to the river with a temperature change of 3°C.

### Heating/ Cooling Loads

To do the heating and cooling loads of the project Hourly analysis program was used. This software is based on ASHRAE standard 62.1-2010

The following steps were done in the software. Location, and climate data were inserted.

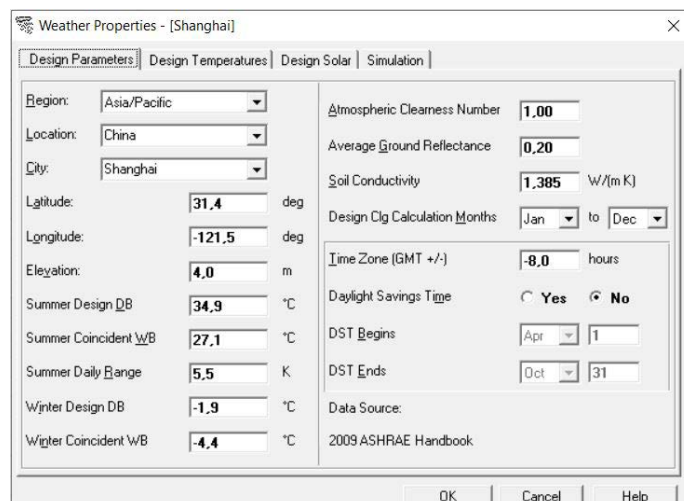

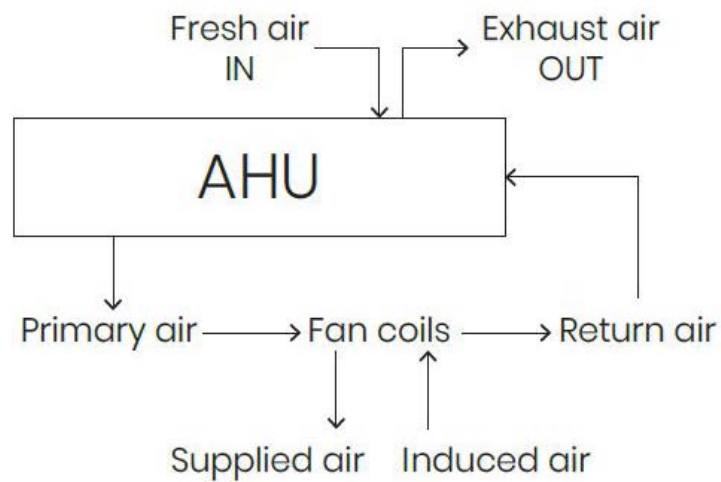

To run the analysis, we split the building in 5 zones, then only one was used for the simulation. The zone was divided by floor and the floor in block to better manage the space inside. The U-values of wall, roof, windows and doors, based on the curtain system, were defines.

Once all the information about the space were defined, we proceeded to insert the data about the power supply.

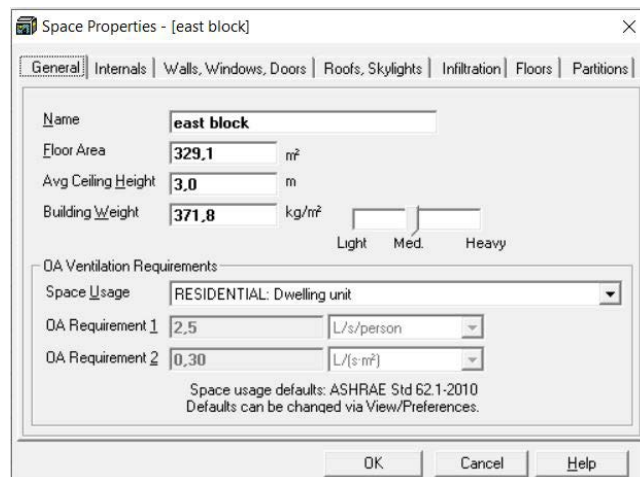

At this point the data corresponding to the spaces was assigned, specification of the system was assigned.

After these steps, design analysis was ran.

## Dedicated Outdoor Air System (DOAS) Sizing Summary for Default System

Project Name: shanghai tower  
Prepared by: PoliMi

06/27/2022  
12:48

### Air System Information

Air System Name ..... **Default System**  
Equipment Class ..... **TERM**  
Air System Type ..... **PKG-FC**

Number of zones ..... **1**  
Floor Area ..... **9071,0** m<sup>2</sup>  
Location ..... **Shanghai, China**

### Sizing Calculation Information

Calculation Months ..... **Jan to Dec**  
Sizing Data ..... **Calculated**

Zone L/s Sizing ..... **Sum of space airflow rates**  
Space L/s Sizing ..... **Individual peak space loads**

### Cooling Coil Sizing Data

Total coil load ..... **157,3** kW  
Total coil load ..... **20,8** L/(s kW)  
Sensible coil load ..... **74,1** kW  
Coil L/s at Jun 1500 ..... **3271** L/s  
Max coil L/s ..... **3271** L/s  
Sensible heat ratio ..... **0,471**  
Water flow @ 5,6 K rise ..... **N/A**

Load occurs at ..... **Jun 1500**  
OA DB / WB ..... **34,3 / 27,1** °C  
Entering DB / WB ..... **34,3 / 27,1** °C  
Leaving DB / WB ..... **15,5 / 15,6** °C  
Bypass Factor ..... **0,100**

### Heating Coil Sizing Data

Max coil load ..... **91,0** kW  
Coil L/s at Des Htg ..... **3271** L/s  
Max coil L/s ..... **3271** L/s  
Water flow @ 11,1 K drop ..... **1,96** L/s

Load occurs at ..... **Des Htg**  
Ent. DB / Lvg DB ..... **-1,9 / 21,1** °C

### Humidifier Sizing Data

Max steam flow at Des Htg ..... **43,13** kg/hr  
Airflow Rate ..... **3271** L/s

Air mass flow ..... **14141,83** kg/hr  
Moisture gain ..... **0,0305** kg/kg

### Ventilation Fan Sizing Data

Actual max L/s ..... **3271** L/s  
Standard L/s ..... **3270** L/s  
Actual max L/(s·m<sup>2</sup>) ..... **0,36** L/(s·m<sup>2</sup>)

Fan motor BHP ..... **0,00** BHP  
Fan motor kW ..... **0,00** kW  
Fan static ..... **0** Pa

### Exhaust Fan Sizing Data

Actual max L/s ..... **3271** L/s  
Standard L/s ..... **3270** L/s  
Actual max L/(s·m<sup>2</sup>) ..... **0,36** L/(s·m<sup>2</sup>)

Fan motor BHP ..... **0,00** BHP  
Fan motor kW ..... **0,00** kW  
Fan static ..... **0** Pa

### Outdoor Ventilation Air Data

Design airflow L/s ..... **3271** L/s  
L/(s·m<sup>2</sup>) ..... **0,36** L/(s·m<sup>2</sup>)

L/s/person ..... **14,87** L/s/person

# CONCLUSION

The project of Live on High on Shanghai, aims to illustrate a new way of living on the high rises with a much considerate design of user needs with reference of traditional Chinese architecture; and the aspects learned from city's urban transformation history. The design is made based on the researches on the existing urban patterns, the history of the city; having the goal to understand this mega metropolis city itself.

In between all the high rise buildings that are built, a different way of living concept formed by main two aspects: The first one to start the architectural role inside the traditional Chinese architecture and than the role it holds much of society and culture. Taking a deeper study on people's life, understanding the habits and forming the architectural program around this habits of living became the main idea to achieve. On traditional Chinese architecture, the research highlights the courtyard it is seen that one element that had come through the history to today's date is the element and the use of common spaces in different functions.

Applying the courtyard theme to a tower resulted on different loggia settlements dedicated to different functions that has been observed on daily lives at estimated user groups. The design of the galleries, with the role of gathering people and leisure, taking advantage of the geometry of the tower, they are placed in four different corners facing different orientations of the city. To accommodate such complexity of intent, the overall volume of the tower must be as clear and essential as possible. Thus, the choice of the column typology as the model for our project. It will take shape through the complex flexible spaces described so far, wrapped by a secondary skin that will define its limits; increasing and decreasing in intensity along with the development of the tower so as to highlight the salient spaces.

To conclude, the justification of any proposal of high rise in such part of the city which is under transformation is made by deep studies on the city, high rise buildings and traditional way of living. Learning from the conflicts of living on high, the unsuccessful trials that has been made, helped the proposal to have a different perspective, coupling mix of functions in strict divisions of the city, offering a possible alternative solution to life on high.
