

a deep pit is dug in the courtyard facing north and make a few ponds in front of it with 40 to 50 cm depth. during the night they fill the ponds with water and by the daytime when the water would be frozen then they crash it into small pieces. later they place all the crushed ice in the pit and refill the ponds with fresh water. after approximately 7 to 8 days a layer of ice with 1m to 2 m will be produced.
